Abstract - Experimental and clinical investigations indicate that antibody production and T-helper 2 (TH2) cytokine pattern, e.g., Interleukine - 4, 10 (IL4, IL10) are dominant during pregnancy. Consequently, The T-helper 1 (TH1) cells activities decrease in pregnancy. Thus the cell-mediated immunity is partially depressed. All these events help fetus as an allograft survive in the mother’s uterus. In our research we measured TH cytokines in the sera of healthy pregnant and non-pregnant women (IL2, IL4, interferon-gamma; IFN-γ). Pregnant women showed significant decrease in mean serum level of IL2 and IFN-γ; this means depression of cell-mediated immunity. This finding explains increased incidence of some of the intracellular infections and survival of the fetus during pregnancy. Acta Medica Iranica 36 (1): 47 - 50; 1998

Key words: T-Helper cell, humoral immunity, cell-mediated immunity, cytokine, interleukine, interferon-gamma, pregnancy, infertility, abortion

INTRODUCTION

Pregnancy is a unique immunologic condition that is accompanied with changes in the immune system (1 - 7). It is increasingly apparent that there is bidirectional interaction between the maternal immune system and the reproductive system during pregnancy (8 - 10). Recent studies show that humoral immune responses are potentiated in the pregnant women, while cell-mediated immunity is decreased during the normal pregnancy (1 - 7, 11 - 13). Recently researchers have focused on the role of TH2-cells subsets and cytokine pattern in pregnancy. Since TH2 cytokines (IL2, IFN-γ) are generally harmful to maintenance of pregnancy, as a consequence the maternal immune system during pregnancy preferentially mounts TH1-biased, resulting in increased susceptibility to certain autoimmune diseases and intracellular infections (1 - 4, 6, 12, 14 - 18).

There are also a number of infectious diseases caused by intracellular pathogens which appear exacerbated by pregnancy, e.g.: HIV associated infections, leprosy, coccidioidomycosis, malaria toxoplasmosis and tuberculosis (1, 12, 19).

Increased incidence of some of intracellular infections and protection of fetus from T-cytotoxic cells' attack which is parallel with increase in humoral immunity rather than cell-mediated immunity, lead us to believe that cytokines production pattern has been changed.

While TH1 activities adventure pregnancy, in order to prevent rejection of the fetus, TH2-type responses will be dominant, so, IL4, IL5 and IL10 productions increase especially in fetomaternial space. These cytokines are able to regulate production of TH1-type responses (1 - 4, 6, 12, 14, 15).

Studies have shown that cytokines, e.g.: IFN-γ and tumor necrotizing factor-α (TNF-α) influence many of process of fertility and related to unexplained infertility as well as spontaneous / recurrent abortions (1, 5, 12, 16).

In the present research TH1 and TH2 cytokine pattern studied in healthy pregnant and non-pregnant women in order to elucidate the nature of the cytokines production pattern in pregnant and non pregnant persons.

MATERIALS AND METHODS

In present study serum samples were collected from 36 healthy pregnant women (in first and second trimester) in obstetrics clinic of Akbarabady hospital and from 30 healthy
Cytokine Pattern of T_{H1} and T_{H2} Cells in Pregnancy

non-pregnant women as the control group. Two groups ages were between 25 to 30 years old. Sera were separated from peripheral blood by centrifugation in the sterile condition and kept in \(-70^\circ\)C until testing. We examined T_{H1} and T_{H2} activities by measuring their cytokine productions specially IL2, IL4, and IFN-\(\gamma\) as representation of their main functions. Determination of the cytokines level in each sample was accomplished using commercially available kits for each cytokine. Kits were based on micro-ELISA sandwich. The detail procedures was that of the manufacture’s recommendations.

RESULTS

Results were statistically analysed using student’s t-test. We found significant decrease in mean serum level of IL2 and IFN-\(\gamma\) in pregnant group.

Mean serum level of INF-\(\gamma\) and IL2 was 603.714 \(\pm\) 137.97 pg/ml and 404.429 \(\pm\) 232.039 pg/ml in pregnant group, respectively. While the serum level of the non-pregnant women was 834.5 \(\pm\) 162.991 pg/ml and 838.668 \(\pm\) 969.923 pg/ml, respectively (Fig. 1) (Table 1).

Our results show that serum level of IL4 did not have any increase in non-pregnant women.

DISCUSSION

We concluded that decrease in serum level of IL2 and IFN-γ in pregnant women may indicate the depression of cellular immunity and explain increased incidence of some of the intracellular infections and also autoimmune diseases seen during pregnancy. This might also explain survival of fetus which is an allograft within immune competent mothers. Imbalance of Th1, Th2 cytokine pattern may be one of the immunologic causes in unexplained infertility and recurrent/spontaneous abortions.

Therefore measuring of Th1 and Th2 cytokines in these cases will help to clarify immune pathogenesis of these abnormalities. If this is true, we might be able to prevent these immunological disorders by immunotherapy in the feature.
